Igor Pro 6 is a powerful, extensible, interactive software environment for experiment with wave shapes, time-series data,. The semiconductor industry is constantly exploring avenues of electrically-powered vehicles in order to achieve the cleanest possible fuel; the greenest engines. One technology, more effective than the others, if it could be better integrated into all daily life objects, is electrically powered microbattery. The Japanese have already integrated the technology into their cars, which run on hydrogen (not hydrogen peroxide, as we have been led to believe). Japanese carmaker Toyota demonstrates in their videos that hydrogen fuel cells use two processes to produce electricity: the first involves the conversion of hydrogen gas into a chemical reaction which generates electricity, and the second is the chemical reaction of the electricity to produce the hydrogen fuel. The first conversion makes sense if the hydrogen is produced at a stationary facility in order to store energy for later use. But when all of the energy for the fuel cell comes from the hydrogen gas itself, then the second process, which is not very efficient, makes no sense. The Japanese engineer Wataru Oikawa is excited about the possibility of electrically powered microbatteries that directly convert the electric current into the fuel. In a paper in the June 8, 2005, issue of The Proceedings of the National Academy of Sciences, Oikawa presents a microbattery design that uses the

familiar alkaline battery cell structure, but from which the two electrodes are replaced by two electrodes of nanostructured material. Oikawa said he has already patented the design. Oikawa said that to produce even the smallest amounts of hydrogen from an alkaline battery requires extremely high temperatures and pressure. Most hydrogen-consuming processes are, and should be, far less energy-consuming and non-polluting. So his hope is to produce hydrogen at ambient pressure and temperature for gas and vehicle applications, to simply replace batteries. Oikawa's battery consists of the battery cell structure, an alkaline electrode, and a nano-structured hydrogen fuel electrode. The alkaline electrode has a three-dimensional porous structure coated with cobalt hydroxide as the electrocatalyst. The nanostructured hydrogen fuel electrode is made from the metal nickel, which can directly produce hydrogen in the presence
